Combining register and survey data in a scenario for long-term care
Sören M. Werner and Thomas Willmann, City of Freiburg, Germany

Abstract

For a projection of long-term care, the City of Freiburg used different data sources. The scenario model combines register data, population forecasts and data from a citizen survey. The paper discusses the scenario model and the key role of the combination of the different data sources. In the end there will be a prospect of an even better use of survey data and how this could improve the projection model.
